Re: GLA 4558 - 9, 11 and 19 Osiers Road

Dear Reece,

## 1. Introduction

This report has been produced to supplement the Flood Risk Assessment document reference 4618-FRA-jk-180726-jk-Rev2-RDCD, to provide additional information and clarification on items raised by the GLA during the Stage 1 consultation for the proposed development at 9, 11 and 19 Osiers Road, Wandsworth.

Within this report risks are expressed as an annual exceedance probability (AEP). This is the percentage probability that a given event could occur in any given year.

## 2. GLA Comments

Following the Stage 1 consultation the GLA made the following comments in an email dated 13<sup>th</sup> August 2019:

Information requested	Location Addressed
<i>2. The surface water drainage strategy for the proposed development does not comply with the London Plan policy 5.13 (and draft policy Sl.13), as it does not give appropriate regard to the drainage hierarchy, greenfield runoff rate and climate change. Further details on how SuDS measures at the top of the drainage hierarchy will be included in the development, and how greenfield runoff rate will be achieved should be provided. Additional attenuation storage volumes calculations, attenuation tank dimensions, and SuDS maintenance information should also be provided.</i>	Section 3.3

<p>3. The proposed development does not comply with the requirements of London Plan policy 5.15 (and draft New London Plan policy SI.15) as no water consumption target has been identified for the residential component of the development.</p>	Section 3.8
<p>9. The calculations of Greenfield runoff rates adopts an urbanisation factor of 0.75, representing partially developed catchment. The Greenfield runoff rate is intended to represent a partially developed catchment (literally a 'green field') and the use of an urbanisation factor greater than zero is incorrect. The applicant should provide revised Greenfield runoff calculations using an urbanisation factor of zero.</p>	Section 3.1
<p>10. The surface water drainage strategy addresses the Drainage Hierarchy, and notes that rainwater harvesting and green roofs would be possible options, and that infiltration is not feasible due to the site geology. Attenuation tanks are proposed as the main SuDS measure, and these are the only measures that are shown on plans. Permeable paving is mentioned but does not appear on landscaping plans. Opportunities for green infrastructure-based SuDS public realm areas have not been considered. This approach does not satisfy the requirements of London Plan policy 5.13 (and draft London Plan SI.13). The applicant should provide more detailed plans including rainwater harvesting, green/blue roofs, permeable paving and green infrastructure-based SuDS such as tree pits and raingardens.</p>	Section 3.4
<p>11. The attenuation tank volume have been estimated using a simplified method, which gives an estimated attenuation requirement of 300m<sup>3</sup> for a design discharge rate of 2.3l/s in a 100 year event with 40% climate change allowance. Section 6.3 of the FRA suggests a range of potential design discharge rates, up to Q<sub>100</sub>. Where a design discharge rate greater than Q<sub>bar</sub> is proposed, more detailed calculations should be provided to show resultant discharge rates in a range of design events up to the 100 year event with 40% climate change allowance.</p>	Section 3.5
<p>12. Section 6.2.1 and 6.3 of the FRA show a 30% climate change allowance for design. This is not consistent with the value adopted in section 6.2.4 or current government climate change allowance guidance for small catchment areas.</p>	Section 3.2
<p>13. No maintenance plan has been included in the drainage strategy. The applicant should include a maintenance plan showing the maintenance and inspection frequency, and maintenance activities for each SuDS measure proposed.</p>	Section 3.6
<p>14. No assessment of the exceedance flow paths has been provided. Additional information should be provided showing that exceedance flow paths, through the site are available in the case of attenuation system blockage or an extreme rainfall event.</p>	Section 3.7
<p>15. The surface water drainage strategy for the proposed development does not comply with London Plan policy 5.13 (a draft policy SI.13), as it does not give appropriate regard to the drainage hierarchy, Greenfield runoff rate and climate change. Further details on how SuDS measure at the top of the</p>	Section 3.3

*drainage hierarchy will be included in the development, and how Greenfield runoff rates will be achieved should be provided. Additional attenuation storage volumes calculation, attenuation tank dimensions, and SuDS maintenance information should also be provided.*

## 3. Proposed SuDS Drainage Details & Calculations

### 3.1. Greenfield Runoff Rates

The FRA proposed a greenfield runoff rate of 2.3 l/s based on a site area of 0.41ha and applying an urbanisation factor of 0.75. Following the GLA's comments on the greenfield calculation this rate has been reviewed and revised to represent the greenfield runoff rate for the site excluding the urbanisation factor. The rates have been calculated using the WINDES MicroDrainage software SUDS function which is based on the FSR method. The calculations for the rates are presented in Attachment D of this report. The table below summarises the greenfield runoff rates for the 50%, 3.3% and 1% annual exceedance probabilities.

Greenfield Runoff Rates		
Annual Exceedance Probability (AEP)	Greenfield Runoff Rate (l/s)	
50% AEP	$Q_{bar}$	0.6
3.3% AEP	$Q_{30}$	1.4
1% AEP	$Q_{100}$	2.0

### 3.2. Climate Change

The climate change allowance is now taken as 40% in line with upper estimate of the current government climate change allowances and the London Plan.

### 3.3. Drainage Hierarchy

In accordance with policy SI.13 of the new Draft London plan which is largely in keeping with policy 5.13 of the London plan, all new developments should utilise Sustainable Drainage Systems (SuDS) unless there are practical reasons for not doing so, and should aim to achieve greenfield run-off rates and ensure that surface water run-off is managed as close to its source as possible in line with the following drainage hierarchy:

- 1) Rainwater use as a resource (for example rainwater harvesting and blue roofs for irrigation)*
- 2) Rainwater infiltration to ground at or close to source*
- 3) Rainwater attenuation in green infrastructure features for gradual release (for example green roofs, rain gardens)*
- 4) Rainwater discharge direct to a watercourse (unless not appropriate)*
- 5) Rainwater attenuation above ground (including blue roofs);*
- 6) Rainwater attenuation below ground;*
- 7) Controlled rainwater discharge to a surface water sewer or drain*

### 8) Controlled rainwater discharge to a combined sewer

The summary below provides site specific comments on how the drainage hierarchy has been followed.

#### 1) Rainwater use as a resource (for example rainwater harvesting and blue roofs for irrigation)

Blue roofs are proposed at podium level as a source control SuDS feature, however, due to the high density nature of the development there is little permeable landscaped area that require irrigation. It is therefore not considered practical to harvest rainwater for the purposes of irrigation. Green and brown roofs provide a degree of storage within the substrate that will naturally be used to irrigate the roof.

#### 2) Rainwater infiltration to ground at or close to source

The site investigation report indicates infiltration is not possible due to the underlying strata and groundwater level. Tanked permeable paving is proposed to the external ground level paved areas.

#### 3) Rainwater attenuation in green infrastructure features for gradual release (for example green roofs, rain gardens).

Green and Brown roofs are proposed at roof level and raised planters at ground level.

#### 4) Rainwater discharge direct to a watercourse (unless not appropriate)

The route to the River Wandle crosses 3<sup>rd</sup> party land and is therefore not considered to be viable

#### 7) Controlled rainwater discharge to a surface water sewer or drain

There are no known surface water sewers in the vicinity of the site.

#### 8) Controlled rainwater discharge to a combined sewer

There are no known combined sewers in the vicinity of the site. Surface water will likely need to be discharged to the designated foul water sewer which is assumed to be combined as existing, subject to Thames Water approval.

## 3. 4. Proposed Sustainable drainage features

In line with the London Plan the SuDS selected for the proposed development should be appropriate for the development and for the location, on this basis the following SuDS features are proposed:

- Blue roofs
- Green/ Brown roofs
- Permeable paving
- Below ground attenuation tank

Blue roofs are proposed at podium level in areas that are not above residential units. It is proposed that blue roofs will be provided in the form attenuation crates between 85mm and 100mm deep and with 95% void ratio. Due to the depth of the attenuation feature the blue roof is assumed to only attenuate rainwater falling directly onto it and would not have the capacity to attenuate rainwater from roof level as well.

Green roofs are proposed at roof level as indicated on drawing T20P14 included in Attachment A. The drawing highlights roof areas that are to be used for photovoltaic modules and green roofs, roof areas that are to be used for photovoltaic modules are not considered viable for green roofs as well.

The use of permeable block paving is proposed on external hard landscaped areas. Due to the lack of infiltration potential the paving would have to be 'Type C – No infiltration' construction. As noted in the drainage strategy, storage in permeable paving is assumed to be provided in the form of a 300mm subbase at 30% void ratio.

At this stage of the design detailed plans of SuDS measures and landscaping features cannot be provided as the design of the building is not at detailed design. However approximate areas and depths of proposed SuDS features and the benefits provided by them have been summarised.

The strategy for implementing and providing detailed design of green infrastructure based SuDS features has been agreed with the Architect, Landscape Architect and Client. However, large scale rainwater harvesting is not practicable for implementation for the project.

### 3.5. Discharge rates

In line with the FRA and CIRIA guidance the peak discharge rate off site is proposed to match the  $Q_{100}$  discharge rate for the 1% AEP rainfall with a 40% allowance for climate change. The 3.3% AEP discharge rate should target the  $Q_{30}$  Greenfield rate and the 50% AEP discharge rate should target the  $Q_{bar}$  greenfield rate for the site.

CIRIA guidance notes that the implementation of 'long term storage' features such as green roofs, brown roofs and permeable paving reduces the volume of discharge off-site. A greater percentage of runoff is prevented from discharging in more frequent storm events due to the process of evapotranspiration and wetting of soil and aggregate, as well as temporary storage provided by the green roof and permeable paving subbase. In addition the SuDS features are a form of 'source control' SuDS which provide treatment to surface water runoff in line with the SuDS management train.

With consideration given to the above the 50% AEP discharge rate will be lower than the  $Q_{30}$  discharge rate due to the use of long term storage features, however the  $Q_{bar}$  discharge rate is considered unreasonable to achieve without introducing a risk of blockage. This is because the size of the flow control orifice will be smaller which in turn increases maintenance issues associated with them.

The 3.3% AEP will be restricted to the  $Q_{30}$  discharge rate and the 1% AEP restricted to the  $Q_{100}$  discharge rate through the implementation of a series of flow control, for example at podium level to attenuation flows from the blue roof as well as a complex flow control prior to discharging off site.

Attachment D provides calculations on the discharge rates for  $Q_{bar}$ ,  $Q_{30}$  and  $Q_{100}$  and the resultant volumes of storage required for each return period. The critical return period, resulting in the largest volume of storage required, estimated to be  $336m^3$  is the 1% AEP with an additional 40% allowance for climate change. The table below summarises how the storage will be provided.

Attenuation Feature	Storage Volume Provided
Below ground attenuation tank	$228m^3$
Permeable Paving subbase	$100m^3$
Blue Roof	$8m^3$

Section 6.2.4 of the FRA notes the required storage volumes based on 2.3l/s discharge rate for up to and including the 1% AEP with a 40% allowance for climate change. The updated calculations storage volumes noted in the table above are similar, albeit slightly higher, as they are based on a 2.0l/s discharge for the 1% AEP with a 40% allowance for climate change.

### 3.6. Maintenance Plan

A maintenance plan for each of the proposed SuDS techniques has been included in Attachment C.

### 3.7. Exceedance Flows

An assessment of the exceedance flow paths based on the existing site levels demonstrates that the exceedance flows will be from the north eastern corner of the site to the southwestern towards the public highway. The topographical survey is included in Attachment B.

In the event of a system blockage or an extreme rainfall event the site levels and surface waters system should be designed to convey runoff away from the building and its users. The diagram below demonstrates the overland flow routes.

Due to the upper climate change limit being used for the drainage design exceedance flows are not expected to be significant. In addition most of the external landscaping will be permeable paving, so a flows generated by a blockage of the surface water system at a particular point in the system would likely drain back into the system at another point, without generating significant flows off site.

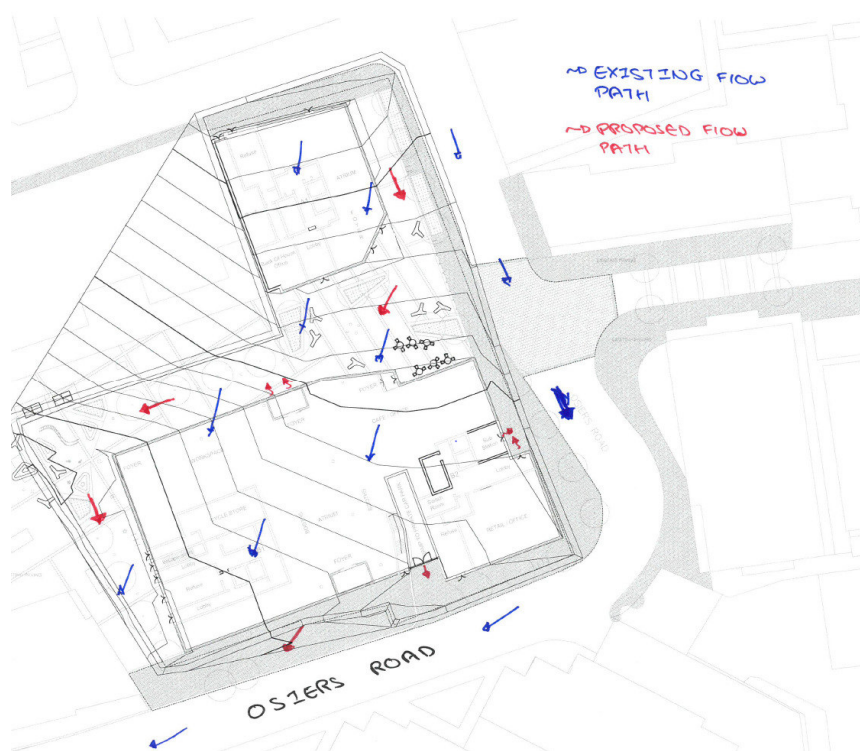

Figure 3.1 Exceedance flow paths

### 3.8. Water Consumption Target

The residential component will be designed so that the mains water consumption would meet a target of 105 litres or less per person per day (excluding 5 litres per person per day for external water use). This target will be met by specifying fittings in accordance with the optional requirement 'fitting approach' as noted on table 2.2 in buildings regulations approved document G.

## 4. Conclusion

It is intended that this report demonstrates the sustainable drainage principles set out for the proposed development and addressed the GLA comments regarding the drainage proposals for the site.

	Deadhead	As needed	
	Check Irrigation/Moisture Levels	To Manufacturer's guidance	
	Fertilising	As needed only	
Blue roofs and associated ancillaries. (This is TBC following appointment of manufacturer)	Inspections of flow control outlets	1 Month	Site Maintenance Contractor/ Specialist Maintenance Contractor
	Inspections of rainwater inlet chambers	1 Month	
	Inspection of hard standing surfaces	8-10 Weeks	
	Removal of silt from chambers	As required	
	Record of inspections/maintenance undertaken to be kept	As required	
Inspection and Control Chambers	Inspect surface structures removing obstructions and silt as necessary. Check there is no physical damage.	3 Months	Site Maintenance Contractor
	Remove cover and inspect ensuring water is flowing freely and that the exit route for water is unobstructed. Remove debris and silt.	1 Year	Site Maintenance Contractor
Inlets and Outlets to SUDS features	Inspect, remove silt and debris	3 months	Site Maintenance Contractor
Geocellular Attenuation Tank	Maintenance to be carried out as necessary	As needed	Specialist Maintenance Contractor

## Attachment D – MicroDrainage Calculations

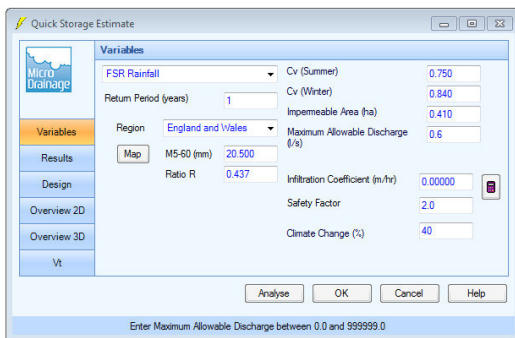

Project No. 4618

Ref: P:\Projects\4618\Documents\Reports\FRA\GLA Response\Attachment D - Micro Drainage Calculations\Quick Storage Estimate.docx

# Osiers Road, MicroDrainage Quick Storage Estimates

Quick Storage Estimate

Micro Drainage

Variables

FSR Rainfall: [Dropdown]

Return Period (years): 1

Region: England and Wales

M5-60 (mm): 20.500

Ratio R: 0.437

Cv (Summer): 0.750

Cv (Winter): 0.840

Impervious Area (ha): 0.410

Maximum Allowable Discharge (l/s): 0.6

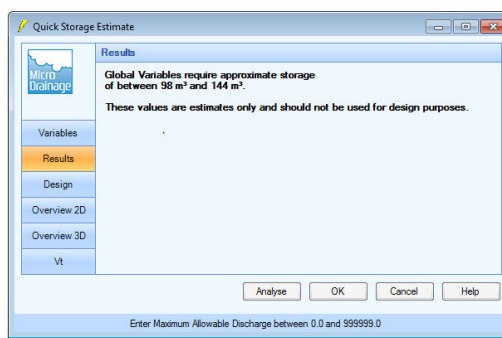

Infiltration Coefficient (m/hr): 0.00000

Safety Factor: 2.0

Climate Change (%): 40

Analyse OK Cancel Help

Enter Maximum Allowable Discharge between 0.0 and 999999.0

Quick Storage Estimate

Micro Drainage

Results

Global Variables require approximate storage of between 98 m<sup>3</sup> and 144 m<sup>3</sup>.

These values are estimates only and should not be used for design purposes.
